

76 of 100 apps could become agent toolkits today

Composio AI Product Ops Intern take-home · Gaurav A Gopalakrishnan · 24 Sep 2026

Live case study	https://random-gau.github.io/composio-app-research/
Source repo + README	https://github.com/random-gau/composio-app-research
Machine-readable results	https://random-gau.github.io/composio-app-research/results.json

The patterns

- **76 build now, 21 with friction, 3 blocked.** All 10 communications apps are open; Support and Marketing are the least open (6 of 10).
- **The most common blocker is a price, not a partner:** 12 of 24 need a paid plan or trial. Only 6 need a partnership or enterprise contract; 4 need an app review.
- **OAuth 2 dominates** (75 apps; main method for 56), and 78 apps also offer a static key or token, so most toolkits need two auth configs.
- **72 vendors already publish their own MCP server.** Ecommerce lags (4 of 10).
- **11 build-now apps have no toolkit page on docs.composio.dev** (e.g. WooCommerce, BigCommerce, Magento, MongoDB Atlas). Composio's /toolkits API also omitted 7 toolkits that do exist.
- **9 apps need outreach**, clustered in ads (Google Ads, LinkedIn Ads), enterprise data (DealCloud, PitchBook) and fintech/marketplaces (Ramp, Amazon SP-API).

The agent

Python pipeline on Composio's own tools (COMPOSIO_SEARCH_WEB, FETCH_URL_CONTENT, /toolkits catalog). Pass 1 researches each app once with a cited URL and verbatim quote per answer. Pass 2 runs five loops: quote re-check, consistency rules, Composio catalog cross-check, a blind verifier from a different model family, and an MCP probe, then re-researches and adjudicates anything flagged. Unresolved fields (30 on 22 apps) go to a human queue.

Verification

	Pass 1	Pass 2 (final table)	Pass 3 (experiment)
Dev sample, 19 apps × 5 fields	75.8%	81.1%	86.3%
Held-out test, 10 new apps	90.0%	92.0%	92.0%

Both samples were checked by hand against vendor docs. Pass 3 (targeted fixes designed on the dev sample) looked better there but did not improve the held-out apps, so it was treated as overfitting and not adopted. Misses, including where the loops made an answer worse (Gladly), are shown on the page.
